## Welcome To DesignBuilder V7

DesignBuilder is a user-friendly modelling environment where you can work (and play) with virtual building models. It provides a range of environmental performance data such as: energy consumption, carbon emissions, comfort conditions, daylight illuminance, maximum summertime temperatures and HVAC component sizes.

# Kako uključiti mode za detaljno modeliranje termotehničkog sustava?

#### Supply Aux HW Sub Loop

The supply Aux HW sub loop includes one or more heating equipments, i.e. water heaters or water heater heat pumps and optionally one or more tempering valves, setpoint managers and pumps.

From here you can:

- Add and connect water heaters or water heater heat pumps, tempering valves, setpoint managers and pumps.
- Navigate down to the components by double clicking on them in the edit screen.
- Edit components by first selecting them so they are highlighted in red then right-clicking in the edit screen and selecting 'Edit selected component' in the right-click menu

Operation: Availability schedule: On 24/7

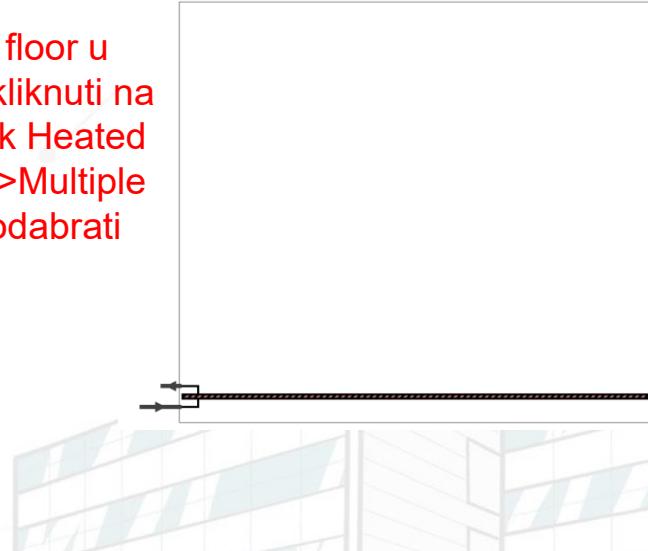

Help Info Data

A Heated floor is a zone component where hot water is circulated through the floor surfaces of the zone. The components must be selected from the list. All floor surfaces must all have an internal source defined on the Construction dialog. This provides EnergyPlus with the information on the position of the hot water pipes within the construction.

**Data**

**Fan Coil Unit**

Fan Coil Units (FCU) are in-room forced-convection hydronic units containing an outdoor air mixer, a fan, a heating coil and a cooling coil. They are mostly used in exterior zones, usually in hotels, apartments, or offices. They may be connected to ducted outside air, or have a direct outside air vent, but they do not have outside air economizers.

The heating or cooling output of the FCU is controlled by varying the air flow rate, the water flow rate, or both. Air flow rate can be controlled by cycling the fan on/off or with a variable speed fan drive. The most common setup is a two or three speed fan with the speed selected by hand. The fan then cycles on/off to control heating / cooling output. The controls are often a wall mounted thermostat with hand selection of heating/cooling and fan speed (off/low/medium/high).

EnergyPlus FCUs cannot be connected directly to a central AHU but this system type can instead be approximated by providing air from an AHU through a direct air ADU in parallel with the FCU.

Autosizable data is shown in blue. This can either have the text 'autosize' or numeric data. In the case where 'autosize' is entered EnergyPlus will calculate an appropriate value before the simulation based on the sizing data provided.

Operation	Availability schedule
	On 24/7

**Help**

**Water Cooling Coil**

The water cooling coil can provide detailed output with simplified inputs. Complex coil geometry is not required for this model, instead the coil is sized in terms of autosizable thermodynamic inputs. The coil requires thermodynamic input such as temperatures, mass flow rates and humidity ratios.

The coil is sized using autosized user design input conditions and the UA values are calculated from the design conditions. A rough estimate of the coil area is provided along with percentage of surface wet and/or dry. This model uses the NTU-effectiveness approach to model heat transfer and has two types of flow arrangements cross-flow or counter-flow.

**Type of analysis**

You can choose between a 'Simple' or 'Detailed' analysis. The simple mode reports the value of surface area fraction wet of the coil as dry or wet. The detailed mode gives the exact value, however the execution time in detailed mode is noticeably higher.

Autosizable data is shown in blue. This can either have the text 'autosize' or numeric data. In the case where 'autosize' is entered EnergyPlus will calculate an appropriate value before the simulation based on the string data provided.

**Model data <admin>**

### Edit Heating Coil -

**Heating Coil**

General	
Name	Block1Izba Fan Coil Unit Heating C
Type	1-Water
Performance input method	2-UA and design water flow rate
Maximum water flow rate (m <sup>3</sup> /s)	Autosize
UA (W/K)	Autosize
Operation	Availability schedule
	On 24/7

**Help**

**Heating Coil**

Water heating coils provide sensible heating of the air only and uses the Effectiveness-NTU algorithm assuming a cross-flow heat exchanger.

There is a choice of input methods: 'UAfactorTimesAreaAndDesignWaterFlowRate' or 'NominalCapacity'. If 'UAfactorTimesAreaAndDesignWaterFlowRate' is selected values are input for UA of the coil and Max Water FlowRate of the coil (and Rated Capacity is ignored). If 'NominalCapacity' is chosen, input for Rated Capacity is defined as the heating capacity in watts of the coil at the rating point (i.e., the rated inlet and outlet waterair temperatures).

Autosizable data is shown in blue. This can either have the text 'autosize' or numeric data. In the case where 'autosize' is entered EnergyPlus will calculate an appropriate value before the simulation based on the sizing data provided.

**Auxiliary Heating Loop**

The Auxiliary Heating Loop loop consists of:

- Supply sub loop which contains one or more water heaters, a pump and a setpoint controller.
- Demand sub loop where hot water consuming equipment such as heating coils, radiators, baseboards and water outlet groups can be added.

This dialog covers the sizing and operation details of the overall loop.

**Load Distribution Scheme**

The Load Distribution Scheme selects the algorithm used to sequence equipment operation in order to meet the plant loop demand. There are 3 options:

- 'Sequential' uses each piece of equipment at its maximum part load ratio and will operate the last required piece of equipment between its minimum and maximum part load ratio in order to meet the loop demand.
- 'Optimal' operates each piece of equipment at its optimal part load ratio and will operate the last component between its minimum and maximum part load ratio in order to meet the loop demand.
- 'Uniform' evenly distributes the loop demand amongst all available components on the equipment list for a given load range.

# DHW Loop

Edit Plant loop -

Plant loop

[General](#) [Plant Equipment Operation](#)

General

Name DHW Loop

Fluid type 1-Water

Plant loop volume (m<sup>3</sup>) Autocalculate

Flow Type

Plant loop flow type 2-Variable flow

Temperature

Maximum loop temperature (°C) 80,00

Minimum loop temperature (°C) 0,00

Flow Rate

Maximum loop flow rate (m<sup>3</sup>/s) Autosize

Minimum loop flow rate (m<sup>3</sup>/s) 0,000000

Load distribution scheme 1-Sequential

Plant loop demand calculation scheme 1-SingleSetPoint

Sizing

Design loop exit temperature (°C) 55,00

Loop design temperature difference (deltaC) 5,00

Loop design temperat

Operation

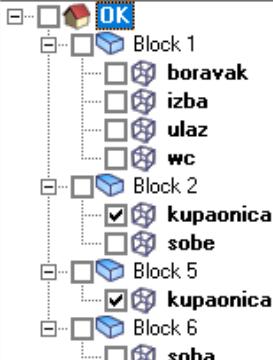

Availability schedule \_obiteljska\_DHW

**General**

Name	DHW Loop Water Heater
Type	1-Mixed
Tank volume (m <sup>3</sup> )	0.08
External Heating Plant Connection	<input type="checkbox"/> External heating plant connection
Temperature Settings	
Setpoint temperature schedule	Domestic hot water setpoint temperature: Always 52
Deadband temperature difference (deltaC)	5.00
Maximum temperature limit (°C)	80.00
Ambient Heat Transfer Settings	
Ambient temperature indicator	2-Zone
Ambient temperature zone	Block2:Kupaonica
Heat Loss Coefficients	
On-cycle loss coefficient to ambient temperature (W/K)	0.00
Off-cycle loss coefficient to ambient temperature	0.00
Heat Loss Fractions to Zone	
On-cycle loss fraction to zone	1.000
Off-cycle loss fraction to zone	1.000
Internal Heating Element	
<input checked="" type="checkbox"/> Internal heating element	
Internal Heating Element Settings	
Heater control type	1-Cycle
Heater maximum capacity (W)	Autosize
Heater minimum capacity (W)	0.000
Heater fuel type	1-Electricity
Heater thermal efficiency	1
<input checked="" type="checkbox"/> Heater part load factor curve	100% efficient
On-Cycle Settings	
Off-Cycle Settings	
User-Side Settings

## Case Studies in Thermal Engineering

journal homepage: [www.elsevier.com/locate/csite](http://www.elsevier.com/locate/csite)

Actual validation of energy simulation and investigation of energy management strategies (Case Study: An office building in Semnan, Iran)

Afshin Fathalian<sup>a</sup>, Hadi Kargarsharifabad<sup>a,b,\*</sup>

### Citat:

investigated only by simulating all factors interfering in energy efficiency of the building [3,4]. Various types of software have been developed in this regard that must be carefully selected [2]. Researcher simulated the energy consumption in a commercial building using EnergyPlus and compared the results with actual values [5]. In a research conducted by Skin and Torkaman [6], heating and cooling loads were simulated for a residential building in a cold and dry climate for 24 h using EnergyPlus and the results were compared to those of actual samples, so that the difference in heating and cooling loads was 3% and 5% respectively. In a study by
